

- 1a) Takes 5 inputs from the text file and mods the "number by 2. If its equal to zero then its even and it not its odd
- 1b) Each line of the input is split in form of number1, operation and number2. A loop is used to iterate through the inputs to check the operations ("If statements") to execute it accordingly
- 2) Contains a nested for loop inside the for loop. The while loop runs until there is no swaps ~~at~~ occurring. While in the for loop an if statement checks wheather the element at the i th index is greater than the $(i+1)$ th index ~~and~~ if true then it swap the elens and sets the swapped variable true which reinstates the while loop.
- 3) Uses selection sort which uses two nested for loops. The first selection sort is used to sort marks. The second one is used to swap the elements if element at i th idx and $(i+1)$ th idx have the same mark ~~and~~ but the element at $(i+1)$ th idx have lower id then it swaps. if the marks are not the same it breaks
- 4) Uses the same idea as no;3 but sorts the names first using lexicographical order then sorts the trains with same name using the latest time to the oldest.
